

CS 162 Programming languages

# Lecture 5: $\lambda$ -calculus

Yu Feng  
Winter 2026

## CS 162 Programming languages

# Your favorite language?

- Assignment
- Booleans, integers, characters, strings, ...
- Conditionals
- Loops
- Functions
- Recursion
- References / pointers
- Objects and classes
- Inheritance

**1368 pages in 2014!**

# The smallest universal language

**Alan Turing**

**Alonzo Church**

The Calculi of Lambda-Conversion, 1936  
ENIAC, 1943

# The next 700 languages

*“Whatever the next 700 languages turn out to be, they will surely be variants of lambda calculus.”*

Peter Landin 1966

# The $\lambda$ -Calculus

Has one and ONLY one feature

- Functions

- ~~Assignment~~
- ~~Booleans, integers, characters, strings, ...~~
- ~~Conditionals~~
- ~~Loops~~
- Functions
- ~~Recursion~~
- ~~References / pointers~~
- ~~Objects and classes~~
- ~~Inheritance~~

# The $\lambda$ -Calculus

More precisely, the only things you can do are:

Define a function

Call a function

“Free your mind”

# Design a programming language

- Syntax: what do programs look like?
  - Grammar: what programs are we allowed to write?
- Semantics: what do programs mean?
  - Operational semantics: how do programs execute step-by-step?

# Syntax: what programs look like

$$e ::= x$$
$$| \lambda x. e$$
$$| e_1 e_2$$

$\backslash x \rightarrow e$  (Haskell)

**fun**  $x \rightarrow e$  (OCaml)

**lambda**  $x. e$  ( $\lambda+$ )

- Programs are expressions  $e$  (also called  $\lambda$ -terms) of one of three kinds:
  - Variable  $x, y, z$
  - Abstraction (i.e. nameless function definition)
    - $\lambda x. e$
    - $x$  is the formal parameter,  $e$  is the function body
  - Application (i.e. function call)
    - $e_1 e_2$
    - $e_1$  is the function,  $e_2$  is the argument

# Running examples

$\lambda x. x$

The identity function

$\lambda x. (\lambda y. y)$

A function that returns the identity function

$\lambda f. f (\lambda x. x)$

A function that applies its argument to the identity

# Semantics: what programs mean

- How do I execute a  $\lambda$ -term?
- “Execute”: rewrite step-by-step following simple rules, until no more rules apply

$e ::= x$   
|  $\lambda x. e$   
|  $e_1 e_2$

Similar to simplifying  $(x+1) * (2x-2)$   
using middle-school algebra

**What are the rewrite rules for  $\lambda$ -calculus?**

# Operational semantics

$$(\lambda x . t_1) t_2 \rightarrow [x \mapsto t_2]t_1$$

$\beta$ -reduction  
(function call)

$[x \mapsto t_2]t_1$  means “ $t_1$  with all **free occurrences** of  $x$  replaced with  $t_2$ ”

```
incl(int x) {  
  return x+1  
}
```

$$(\lambda x . x + 1) 2 \rightarrow [x \mapsto 2]x + 1 = 3$$

```
incl(2);
```

$$[x \mapsto y]\lambda x . x = \lambda x . y \quad \times$$

**What does free occurrences mean?**

# Semantics: variable scope

The part of a program where a variable is visible

In the expression  $\lambda x. e$

- $x$  is the newly introduced variable
- $e$  is the scope of  $x$
- any occurrence of  $x$  in  $\lambda x. e$  is bound (by the binder  $\lambda x$ )

$\lambda x. x$

$\lambda x. (\lambda y. x)$

$x$  is bounded

$x y$

$\lambda y. x y$

$(\lambda x. \lambda y. y) x$

$x$  is free

An occurrence of  $x$  in  $e$  is **free** if it's *not bound* by an enclosing abstraction

# Semantics: free variables

An variable  $x$  is free in  $e$  if there exists a free occurrence of  $x$  in  $e$

We use “FV” to represent the set of all free variables in a term:

$$FV(x) = x$$

$$FV(\lambda x. e) = FV(e) \setminus x$$

$$FV(e_1 e_2) = FV(e_1) \cup FV(e_2)$$

$$FV(x y) = \{x, y\}$$

$$FV((\lambda y. x y)) = \{x\}$$

$$FV((\lambda x. \lambda y. y) x) = \{x\}$$

If  $e$  has no free variables it is said to be closed, or combinators

# Semantics: $\beta$ -reduction

$$(\lambda x . t_1) t_2 \rightarrow [x \mapsto t_2]t_1$$

$\beta$ -reduction  
(function call)

$[x \mapsto t_2]t_1$  means “ $t_1$  with all **free occurrences** of  $x$  replaced with  $t_2$ ”

$$[x \mapsto s]x = s$$

$$[x \mapsto s]y = y (x \neq y)$$

$$[x \mapsto s]\lambda y . t_1 = \lambda y . [x \mapsto s]t_1 (y \neq x \wedge y \notin FV(s))$$

$$[x \mapsto s]t_1 t_2 = [x \mapsto s]t_1 [x \mapsto s]t_2$$

# Semantics: $\alpha$ -renaming

$$\lambda x . e =_{\alpha} \lambda y . [x \mapsto y]e$$

- Rename a formal parameter and replace all its occurrences in the body

$$\lambda x . x =_{\alpha} \lambda y . y =_{\alpha} \lambda z . z$$

$$[x \mapsto y]\lambda x . x = \lambda x . y \quad \text{✗}$$

$$[x \mapsto y]\lambda x . x =_{\alpha} [x \mapsto y]\lambda z . z = \lambda z . z \quad \text{✓}$$

# Currying: multiple arguments

$$\lambda(x, y) . e = \lambda x . \lambda y . e$$

$$(\lambda(x, y) . x + y) \ 2 \ 3 =$$

$$(\lambda x . \lambda y . x + y) \ 2 \ 3 = (\lambda y . 2 + y) \ 3 = [y \mapsto 3]2 + y = 5$$

Transformation of multi-arguments functions to higher-order functions is called currying (in the honor of Haskell Curry)

# TODOs by next lecture

- Install OCaml/ $\lambda^+$  on your laptop
- Continue  $\lambda$  calculus next Wed
